Anencephaly is a congenital malformation of the central nervous system that results from the failure of closure of the cranial end of the embryologic neural tube, usually occurring between the 23rd to 26th days after conception. Anencephaly represents 40% of neural tube malformations, which is the second leading cause of nervous system abnormalities after spina bifida. The prevalence rate is 1/1,000. The diagnosis is made by the 1st trimester ultrasound between the 11th and 14th weeks. The causes are multifactorial (iatrogenic, toxic, metabolic, nutritional and exceptionally chromosomal).

Case Report

Mrs. KD, 24-year-old, rural geographical origin, no notion of consanguinity, gravida 2, para 2. Her G1 was by vaginal delivery with episiotomy of a live born male of 3050 g, G2 is the current pregnancy estimated at 36 weeks given by her last menstruation period. At 25 weeks of the pregnancy, she had gestational diabetes put on insulin therapy in the form of twice daily injections of insulin Glulisine and once daily injection of insulin Lispro was started and dietary advice given, with notion of taking fenugreek and without taking any folic acid in preconception or in the 1st trimester. Came to obstetric emergencies at the start of labor. There was no other significant past, obstetric, or surgical history. On general examination, the patient was clinically stable, height at 157 cm, weight at 80 kg, no edema of the lower limbs, blood pressure at 11/06 cm Hg, 88 bpm, 98% saturation and temperature at 36.7. Obstetric examination: active uterine contractions, 35 cm uterine height, the fetus was in longitudinal position, an active fetal heart beat, on vaginal examination a soft median cervix dilated to 2 cm cleared to 70% intact membrane in cephalic presentation. Emergency ultrasound reveals a single-fetal pregnancy, positive cardiac activity in cephalic presentation with anencephaly, a hydramnios with large cistern at 14 cm. The patient was transferred to the delivery room with monitoring. After 3 hours of labor, a vaginal delivery without instrumental extraction of a newborn male birth weight 3250g, Apgar score 6-7 at first and fifth minutes, respectively. A poly malformative syndrome: Clubbed feet, hands boots, hydrothorax and ventricular septal defect. The post-partum period without anomalies. Death of the newborn at H7 of life.

Discussion

Anencephaly is a defect in the closure of the neural tube during fetal development. A baby born with anencephaly is usually blind, deaf, unconscious and analgesia. It is one of the most common types of neural tube defect, after spina bifida, affecting approximately 1 in 1,000 pregnancies. Diagnosis is made by 1st trimester ultrasound between 11th and 14th week of amenorrhea by the demonstration of encephaly which results in the non-visualization of the ossification of the cranial box and therefore the impossibility of measuring the biparietal diameter. Primary prevention of neural tube closure abnormalities by taking folic acid during the periconceptional period has been shown to be effective. Neural Tube Defects (NTDs) (encephaly, spina bifida, encephalocoele) are the most common congenital malformations after heart and orofacial malformations [1]. Their causes remain obscure until now. In Morocco, the prevalence is around 10 cases per 10,000 births each year. Studies have shown that woman who has had a first affected child has a higher risk than the rest of the population of having a second affected child [2]. In the study by Panduranga et al. [3] all cases were detected between the 16th and 34th week of gestation with a mean gestational age of 21 weeks. As for Shilpa et al. [4] reports an average age of diagnosis of 22 weeks, varying between the 20th and 30th week of amenorrhea (WA). The study by Emre et al. [5] diagnosed anencephaly in 28 fetuses between 11 and 36 weeks old. The mean age of diagnosis was 18 weeks. According to Nidaa et al. [6] the mean gestational age at diagnosis was 21 + 4 WA with an interval between 13 + 4 and 32 + 4 WA. Neural Tube Defects (NTDs) are more common in maternal insulin-dependent diabetes in the first trimester of pregnancy (Figure 1). The prevalence of these malformations varies from 4% to 15% (2.1% in the general population). The increased risk of malformation appears for modest hyperglycemia values. In absolute value, this risk drops from 2% for an HbA1c of 5.5%, to 6% for an HbA1c of 9% [7]. Fenugreek (Trigonellafoenumgraecum L.), in Arabic Helba, is one of the oldest medicinal and culinary plants, it is widely used in Morocco. It is an annual herb belonging to the Fabaceae family that is found all over the world, but it is of Mediterranean origin. In herbal medicine, the seeds of the plant are indicated in diabetics, for controlling glucose and cholesterol levels as well as for pregnant and lactating women [8,9].

In the Maghreb region, it is used in the treatment of wounds, diarrhea, acne, dehydration, anemia, bronchitis, rheumatism, stomach aches, constipation and arterial hypertension, either in the form of decoctions or of seeds reduced to flour and mixed with the honey [10]. The teratogenicity effects of fenugreek in humans and animals have been demonstrated in several prospective studies. Also, cases of pronounced birth defects such as hydrocephalus, anencephaly, cleft palate and spina bifida have been found in women who consumed fenugreek seeds during pregnancy. Variously several studies have shown that fenugreek is neuroprotective [11,12] although, the developing nervous system appears to be particularly sensitive to the toxicity of fenugreek, as previously reported in Moroccan studies showing that children are more likely to develop encephalopathy such as hydrocephalus, anencephaly and spina bifida. Antenatal diagnosis of anencephaly in the first trimester is most successful for fetal abnormalities. In the second trimester ultrasound, the typical appearance of anencephaly is a sign of “frog eyes”, due to the absence of visible brain tissue above the eye sockets. Hydramnios is defined as a pathological increase in the volume of amniotic fluid during pregnancy, the diagnosis is made by ultrasound (Figure 2). Hydramnios is associated with anencephaly in 30% to 50% of cases. The contributing factors include secretion of cerebrospinal fluid into the amniotic cavity, lack of normal swallowing, lack of absorption of amniotic fluid by the hypoplastic lungs and excessive urine production due to lack of antidiuretic hormone. Hydramnios is the most common presentation of anencephaly before child birth. Anencephaly is a uniformly lethal anomaly. It appears to be of multifactorial origin, so they are advised to consume foods rich in folic acid at least 3 months before planning their pregnancy, and to maintain an appropriate intake if they are of child bearing age or patients desirous of birth. Following studies carried out on primary and secondary prevention, Canadian, British and American organizations recommend that women of childbearing age consume 0.4 mg to 0.8 mg/day of folic acid to reduce cases of anencephaly. For women who already have an affected child, the recommended dose is between 0.8 mg and 4 mg.

Conclusion

Anencephaly is a lethal malformation characterized by an absence of closure of the anterior of the neural tube with aplasia of the
cortical architecture and absence of formation of the cranial box. It is the second neural tube defect after spina bifida. Its antenatal diagnosis is mainly based on obstetric ultrasound. The prognosis for anencephaly is grim. It is a uniformly lethal defect. Termination of pregnancy is the most logical approach, but is not practiced in our context due to religious beliefs. Unfortunately, in the absence of curative treatment, prevention is therefore essential and creating awareness among the people about the preventable causes of nutritional deficiency. Therefore, folic acid plays an important role in pre-conception or in the 1st trimester.
